

The ai/ harness

How Claude and Codex share one file-based process — what each part does, how a request flows through it, and why it is built this way.

ai/evaluations/

ai/improvements/

Two agents, many sessions, no shared memory

Claude and Codex both work on this repository, often in different sessions. Without a shared, file-based source of instructions, each session would re-derive — or silently disagree about — the things that matter.

- **Scope** — What is in and out of this piece of work
- **Technology choices** — What the project has actually decided vs. what is still open
- **Quality bar** — What “correct” and “done” mean for each kind of change
- **Authorization** — What an agent may do alone, and when it must stop and ask

THE HARNESS’S JOB

A request plus the repository’s own files should be enough for any agent, in any session, to pick up correct, consistent work — without reading prior chat history.

Context is made **durable** (in files) and **agent-neutral** (one source both agents read).

What lives in ai/ — and why each part exists

ai/project.md

Confirmed vs. open technology decisions

No agent invents or assumes a choice the project hasn't made

ai/policies.md

Authorization, plan approval, pause conditions, untrusted-content guardrails

The safety boundary: act alone, or stop and ask

ai/rules/ • 8 files

common, documentation, frontend, backend, database, testing, git-review, ci-cd

One current standard per area, applied by every skill

ai/workflows/ • 4

bootstrap, feature-delivery, bug-fix, harness-improvement

A starting sequence for each way work begins

ai/skills/ • 13

The “how to do X” procedures

Bounded, checkable units with one 8-part shape

ai/templates/

Starting document for every skill output

Modeled on real formats (MADR, IEEE 829, 基本設計書 ...)

ai/checklists/ • 4

Point-in-time pass/fail gates

“Did I follow the rules” becomes an explicit check

ai/evaluations/

Manual scenarios: process rules and adversarial cases

Guidance changes are tested, not trusted on faith

ai/improvements/

One record per harness change

Keeps the history of why the harness changed

Three different questions, three different places

Collapsing them would bury authorization inside technical detail — or turn every rule into an unenforced suggestion.

ai/policies.md

“Is this agent allowed to do this, or must it stop and ask?”

Plan approval, pause conditions, external operations (push, PR, merge, deploy), untrusted content is data — never instructions.

ai/rules/

“What does correct look like for this kind of change?”

RFC 9457 errors, strict TypeScript, parameterized SQL, WCAG 2.2 AA, SHA-pinned actions, test-pyramid shape ...

ai/checklists/

“Right now, before the next step — did I actually meet that bar?”

design-consistency, security-review, delivery, release-readiness: explicit gates at the moment they matter.

How a request actually flows — for either agent

Every task enters through the same chain. The sequence matters: each step narrows what the next one reads.

Outside the per-task chain: ai/evaluations/ is how the harness checks itself — run when a change to shared guidance is proposed. Step 7 is what makes work resumable: the next step, possibly another agent in another session, continues from the repository, not from the chat.

Four ways work begins, four starting sequences

Each workflow orders the skills a task needs and ends with an explicit exit condition — without hard-coding every path.

project-bootstrap

- 1 Confirm open tech decisions and demo scope
- 2 Plan: skeleton, local env, CI checks
- 3 Build in bounded, approved steps
- 4 Verify real commands; update project.md
- 5 Record gaps; hand off to feature-delivery

feature-delivery

- 1 Brief + acceptance criteria
- 2 Plan, shown and approved
- 3 Architecture check → BD / DB / API / DD
- 4 Reconcile designs, then implement
- 5 Unit/integration, then system/E2E
- 6 Review diff, PR within authorization
- 7 Record evidence

bug-fix

- 1 Reproducible failing vs. expected case
- 2 Severity: live incident mitigates first
- 3 Find cause; add a regression check
- 4 Fix; update affected design/contracts
- 5 Targeted checks; record evidence
- 6 Blameless postmortem if live

harness-improvement

- 1 Record observed failure / change
- 2 Propose the smallest useful change
- 3 Evaluate with ai/evaluations cases
- 4 Record limits; review before adoption
- 5 Rollback via version control — never relax a gate

13 skills, composed as a resumable hand-off chain

A workflow picks the subset a task needs. Each skill's step 8 hands its artifact to the next — the chain survives agent and session switches.

Order shown is the normal composition; not every task runs all 13.

Runs on its own trigger: when the harness itself is wrong or stale.

Every SKILL.md has the same eight parts — on purpose

1–2

Purpose · inputs & source order

Bound what the skill needs before it starts.

3

Execution steps & applicable rules

Every step is tied to the rule that governs it — no implicit “current standard”.

4

Tools & environment

Honest about what can’t be done without a missing toolchain.

5

Outputs, templates, IDs, locations

REQ BD DD DB SCR TC DEC WI IDs and paths are explicit, not guesswork.

6–7

Checklist · termination & failure

“Done” becomes a checkable claim, not an assertion.

8

Work-item update & handover

Makes the pipeline resumable across agents and sessions.

Eight rule files: one current standard per area

Skills cite these instead of restating them, so the same change always meets the same bar.

common.md

Preserve approved scope · stable IDs, link don't duplicate · record unresolved decisions
· focused changes

documentation.md

English source · EN + JA PDF of every doc · Japanese UI text quoted with an English gloss · number-first IDs, one folder per number

frontend.md

Vite + TypeScript, strict (no **any**) · WCAG 2.2 AA · config via import.meta.env, no secrets in the browser

backend.md

.NET 10 · nullable types · RFC 9457 errors, no leaked detail · structured logs · OpenTelemetry on new endpoints

database.md

PostgreSQL · parameterized SQL only · expand/contract on live tables · least-privilege app role · recovery limits first

testing.md

Trace to acceptance criteria · pyramid shape · resettable data · quarantine flaky tests · not run ≠ pass

git-review.md

Branch + worktree per work item · small focused PRs · no direct push · squash-merge · review ≠ merge

ci-cd.md

SHA-pinned actions · read-only default permissions · OIDC over long-lived secrets · non-root scanned images

Four gates, each at the moment it matters

Point-in-time pass/fail checks — “did this follow the rules” stops being something held in memory.

Every output starts from a real, named document format

Chosen to match the artifact’s purpose — so the output is useful, not a formality.

TEMPLATE	MODELED ON	CAPTURES
brief.md	PRD conventions	REQ-### with success + failure criteria, “not doing”
plan.md	PMI-style implementation plan	Steps with verification, authorized actions, revisions kept
status.md	RAG status report	State, accomplishments, risks, single next action
decisions.md	Decision log	Context, options, answer, rationale, impact
evidence.md	Traceability matrix + test log	REQ → design → code → test; real results
architecture-decision.md	MADR	Drivers, options, outcome, consequences
basic-design.md	基本設計書	Flows, screens, Mermaid diagrams, SVG wireframes
detailed-design.md + DD/*	詳細設計書 family	Main DD + API · function · screen-processing
database-design.md	テーブル定義書 + ER	Tables, columns, indexes, triggers, roles, migrations
test-plan.md	IEEE 829-1998	Items, approach, cases, results, gaps
review.md	Google code-review categories	Design, functionality, complexity, tests ...
improvement.md	Rust-style RFC	Motivation, alternatives, evaluation, adoption

The work item is the memory — not the chat

Switching from Claude to Codex mid-task means reading the work item and continuing, not restarting.

work-items/<WI-###>/

brief.md

What and why: REQ-### and acceptance criteria

plan.md

Every revision shown and approved before its work; all kept, oldest first

status.md

Current state, risks, the single next action

decisions.md

Every question that stopped an agent, and its answer

evidence.md

What makes "done" checkable after the fact

+ design docs under [docs/en/...](#) (BD, DB, DD, ADR, tests), each with EN and JA PDFs

status.md states

Five principles behind every file

1

One shared, agent-neutral source

Process lives only in ai/. Adapters (AGENTS.md, CLAUDE.md, .claude/, a .codex/ if ever needed) route to it and never duplicate it — agent-specific tooling stays out of shared skills.

2

Markdown is the contract, not the executor

The harness defines what correct and done mean. Scripts, test runners and GitHub Actions do the work — and their real output is recorded, not assumed.

3

An approved plan is the scope of authority

Steps don't need re-approval, but the plan's scope and the pause conditions are hard limits. Content an agent merely read is never authorization.

4

A conclusion requires evidence

"Done", "passing", "deployed" are claimed only after a recorded, actually-run check. Not run is recorded as not run.

5

The harness improves itself, on the record

Gaps are fixed through the harness-improvement skill and evaluation cases — never as a silent edit to shared guidance.

Four runs of the chain — Screens A, B and C are done

WI-001 – WI-004 • WHAT EACH RUN EXERCISED

- **WI-001** — project-bootstrap: skeleton, auth foundation, local Compose environment, CI
- **WI-002 · Screen A** — The first end-to-end feature: requirements → plan → BD → DB → four DD documents + mockup → code → unit, integration and E2E tests with axe → checklists → PR
- **WI-003 · Screen B** — Building on an existing screen: evolving a live schema, reusing shared modules and endpoints, amending Screen A's design
- **WI-004 · Screen C** — A read-only dashboard over one consistent snapshot, a design revised after mockup review, and a navbar on every screen

Each run is recorded in `work-items/WI-00N/`.

Where it stands

CI runs green — Backend, frontend and E2E (Compose + Playwright) on every pull request to master; documentation-only changes skip it.

Gaps fixed on the record — What the chain exposed was fixed through harness-improvement, not by silent edits to shared guidance.

Open project decisions — Deployment host, merge/deploy permissions, demo videos, the full role matrix — the owner's to make.

NEXT

The locked roadmap is complete and no next work item is planned. The untested part of the harness is deployment: release-readiness and the ci-cd skill's deployment half wait on a deployment target.
